

SCHOTTKY BIPOLAR LSI MICROCOMPUTER SET

3216 PARALLEL BIDIRECTIONAL BUS DRIVER

The INTEL Bipolar Microcomputer Set is a family of Schottky bipolar LSI circuits which simplify the construction of microprogrammed central processors and device controllers. These processors and controllers are truly microprogrammed in the sense that their control logic is organized around a separate read-only memory called the microprogram memory. Control signals for the various processing elements are generated by the microinstructions contained in the microprogram memory. In the implementation of a typical central processor, as shown below, the microprogram interprets a higher level of instructions called macroinstructions, similar to those found in a small computer. For device controllers, the microprograms directly implement the required control functions.

The INTEL 3216 is a high-speed 4-bit Parallel, Bidirectional Bus Driver. Its three-state outputs enable it to isolate and drive external bus structures associated with Series 3000 systems

The 3216 driver and receiver gates have three state outputs with PNP inputs. When the drivers or receivers are tri-stated the inputs are disabled, presenting a low current load, typically less than 40 μ amps, to the system bus structure.

High Performance—20 ns typical propagation delay
Low Input Load Current—0.25 mA maximum
High Output Drive Capability for Driving System Data Busses
Three-State Outputs
